

# Assessment of Rain Impact on the Aquarius Salinity Retrievals

T. Meissner, F. Wentz, J. Scott, K. Hilburn

Remote Sensing Systems

*meissner@remss.com*

**2014 Aquarius / SAC-D Science Team  
Meeting**

November 11- 14, 2014

Seattle. Washington, USA

Remote Sensing Systems   
[www.remss.com](http://www.remss.com)

# Outline

1. MWR
2. Atmospheric Effects
3. Rain Splashing Effects
4. Rain Induced Freshening
5. Freshwater Lensing
6. Rain Impact on Calibration Loop
7. Summary

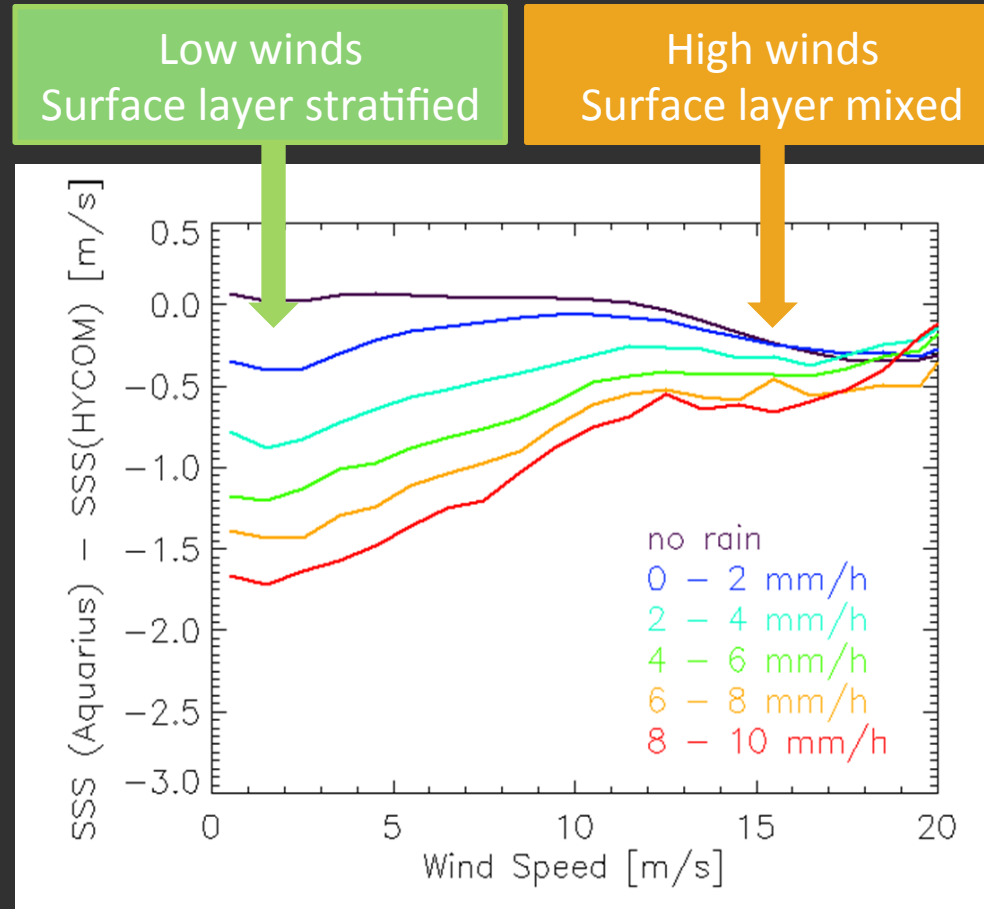

# MWR Rain Rates

- Available at RSS FTP site
  - [ftp://Aquarius\\_mwr:mar23vista36@ftp.remss.com/aquarius\\_mwr/rss\\_l2c\\_h5/](ftp://Aquarius_mwr:mar23vista36@ftp.remss.com/aquarius_mwr/rss_l2c_h5/)
- Space and time collocated to Aquarius L2 swath.
- Format:
  - HDF5
  - same structure as Aquarius ADPS L2 files
  - same name convention for granules
- Variables
  - time, latitude, longitude (matches ADPS L2)
  - cloud water, rain rate, liquid water attenuation at L-band
  - wind speed, water vapor
- Documentation on processing algorithm and file content
- PO.DAAC ?
- Use in Aquarius
  - For analysis only. Not part of L2 processing.
  - Rain Flagging
  - Rain Rates: not very good (37 GHz channel saturates)

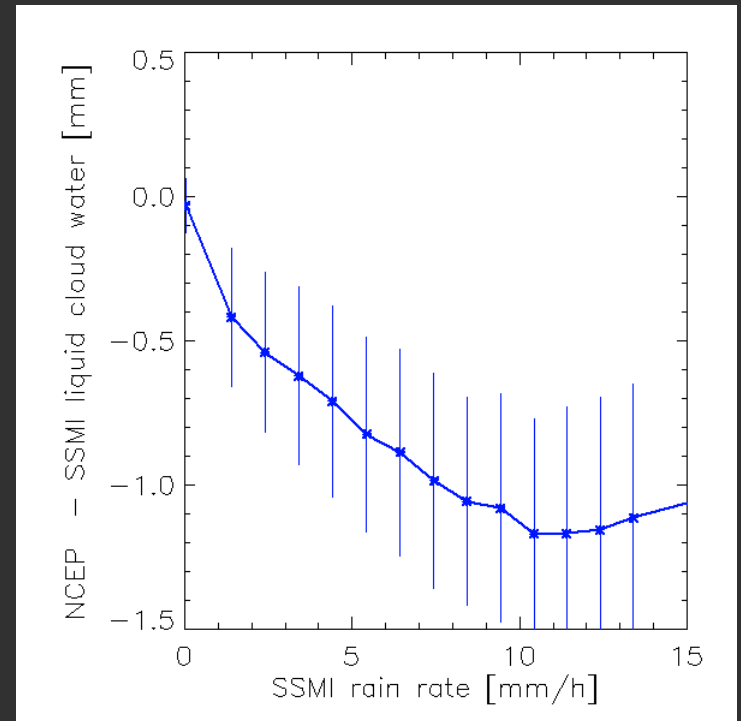

# Rain Induced Effects (1)

1. Real freshening
  - Aquarius (few cm of surface) versus ARGO or HYCOM (5 m depth)
2. Atmospheric absorption
  - Aquarius L2 SSS retrieval uses cloud water from NCEP for atmospheric correction.
3. Surface splashing?
4. SST bias correction
  - Has been applied

We will now show that about 80-90% of the observed effect is mostly due to rain freshening.

# Atmospheric Correction

- Aquarius uses NCEP liquid cloud water for atmospheric rain correction.
- How good is NCEP?
- NCEP misses most of the rain.
- It underestimates the cloud water by close to 100% and thus it is basically useless in rain.

# Impact on Salinity Retrieval

- Assume that SSM/I gives correct cloud water.
- Atmospheric absorption increases TB and thus gives a SSS that is too low.
- The atmospheric rain correction algorithm is supposed to correct that.
- NCEP underestimates the cloud water content and therefore undercorrects the atmospheric effect.
- Conclusion:  
**Our current Aquarius V3.0 SSS is too low/fresh in rain.**
- 0.2 psu in high rain.

# What to do about it?

- Consider using different cloud water auxiliary field for atmospheric rain correction.
- MWR
  - this was the original plan
  - dead
  - MWR rain rates are not very good (no 18 GHz channel, saturation)
- RSS V7 products: SSMIS F17, WindSat, TMI, GMI
  - collocates well with Aquarius (1 hour)
  - but not completely
  - leaves small holes
- **CMORPH**
  - **almost global (lat<60°)**
  - **gives rain accumulation not cloud water**
  - **need to transform into cloud water absorption**
- Match resolution to Aquarius?

# Rain splashing: Wind Speed

- When compared to NCEP the scatterometer (HH- pol) wind speed shows an increase at low wind speeds and high rain rates.
- Likely due to surface splashing.
- NCEP wind speed best ground truth in rain?
- **How does that effect the salinity retrievals in rain?**

# Rain splashing: Surface emissivity

Analyze X-pol:  $X = \beta \cdot H - V$

Combination of V-pol and H-pol that is insensitive to SSS

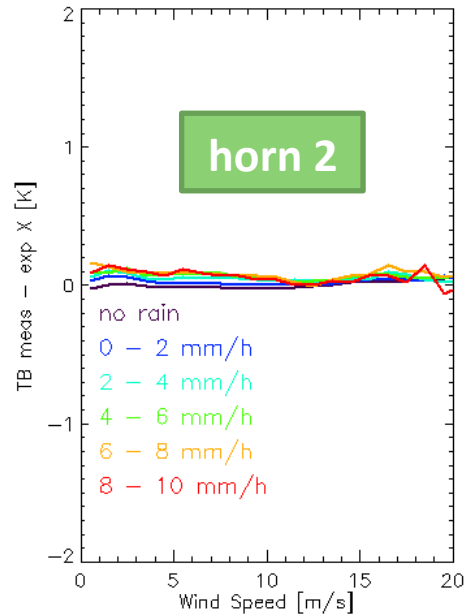

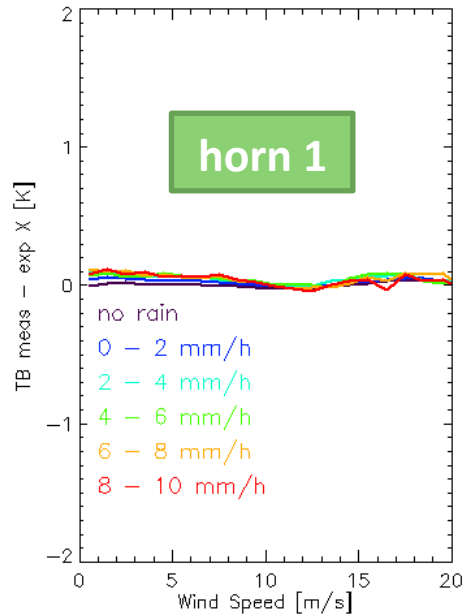

$\beta = 1.18$  (inner horn),  $1.33$  (middle horn),  $1.54$  (outer horn)

It is however, very sensitive to roughness

after removing wind induced (no-rain) emissivity using  
scatterometer wind speed

- Very little rain induced excess emissivity on X-pol.
- Part of the little effect we are seeing could be actually due to undercorrecting the atmospheric effect.
- **Scatterometer wind is used in roughness correction.**  
**Scatterometer wind is proxy for roughness.**
- The results indicate that it is NOT warranted to perform a "rain splash correction" in the ADPS algorithm by forcing the Aquarius SSS to HYCOM.

# Rain Induced Effects (2)

About 80-90% of the observed effect is due to rain freshening.  
Consistent with SMOS finding (J. Boutin et al.)

# Rain Measurement and Filtering

- **CONAE Microwave Radiometer (MWR): K and Ka –band**
  - On Aquarius platform
  - Allows rain measurement at the location and time of Aquarius observation
  - Allows rain flagging: Aquarius observation rain free
- **Microwave Imager**
  - SSMIS (F17), WindSat: 1 hour within Aquarius (same equatorial crossing time)
  - TMI: crossing time shifting relative to Aquarius
  - Can detect rain within time window of Aquarius observation

# Rain Freshening in Tropics

## Aquarius versus HYCOM, ARGO, moored Buoys

# Freshwater Lensing

## Rain Rates from Microwave imager

**Rain within 1 hour of  
Aquarius**

Freshening at surface  
compared with 1m/5m

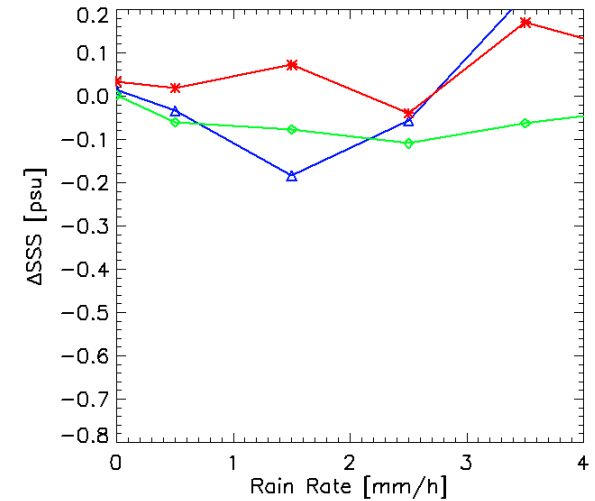

**No rain at Aquarius  
Rain 0 - 1 hour before AQ**  
Freshwater lensing visible

**No rain within 1 hour before  
Aquarius**

**Rain 1 - 12 hours before AQ**  
upper layer has mixed

**Aquarius – PMEL (1m)**

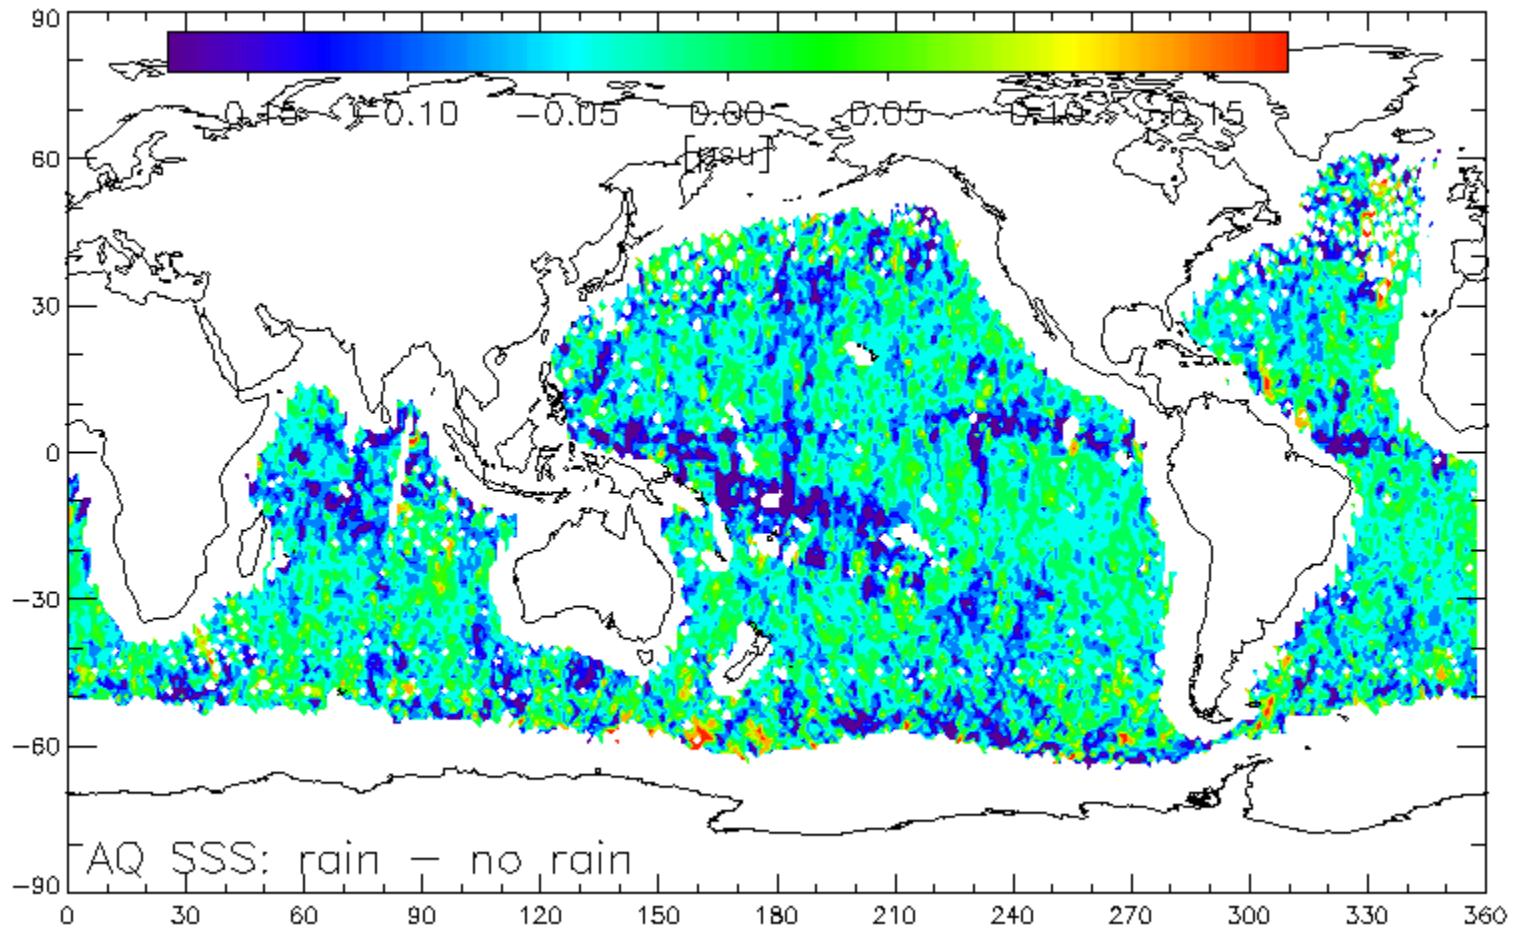

**Aquarius – ARGO (5m)**

**Aquarius – HYCOM (5 m?)**

# Rain Impact on Sensor Calibration

- V3.0 sensor calibration:
  - Matches global 7-day average of Aquarius with HYCOM
  - Does not do rain filtering.
- Consequence: The V3.0 Aquarius SSS are too salty
  - Global bias.
  - Stratification in tropics:  
Aquarius sees rain freshening, which is real, but HYCOM does not. It therefore blames the mismatch to the sensor calibration.
  - The correct way would be to filter Aquarius observations for rain before matching them to HYCOM (or ARGO).
- How much does that amount to?
- Study: Computed monthly climatology of non-rain filtered minus rain filtered Aquarius observations.
  - Time frame where MWR is available for rain flagging.
  - In addition use MW imagers (SSMIS, WindSat, TMI) to filter out rain within 1 hour before Aquarius observation.

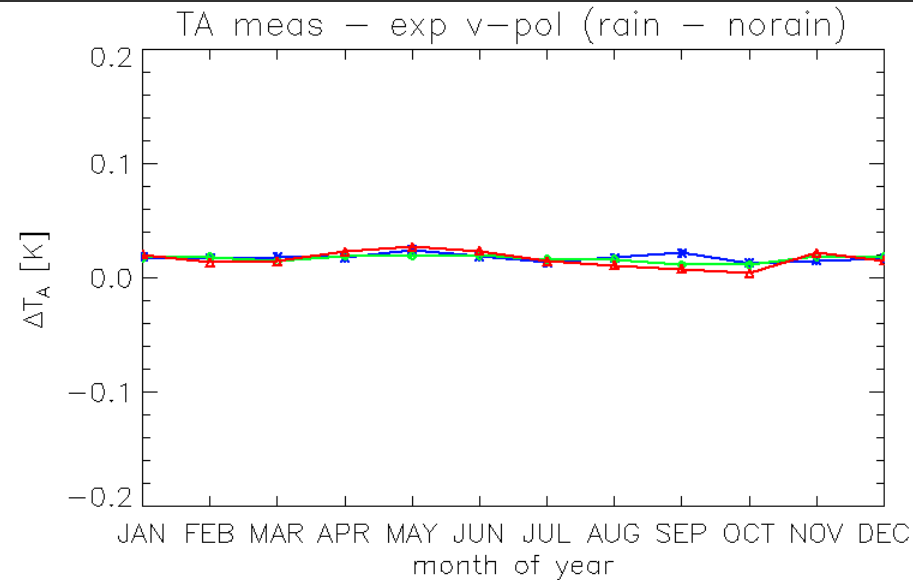

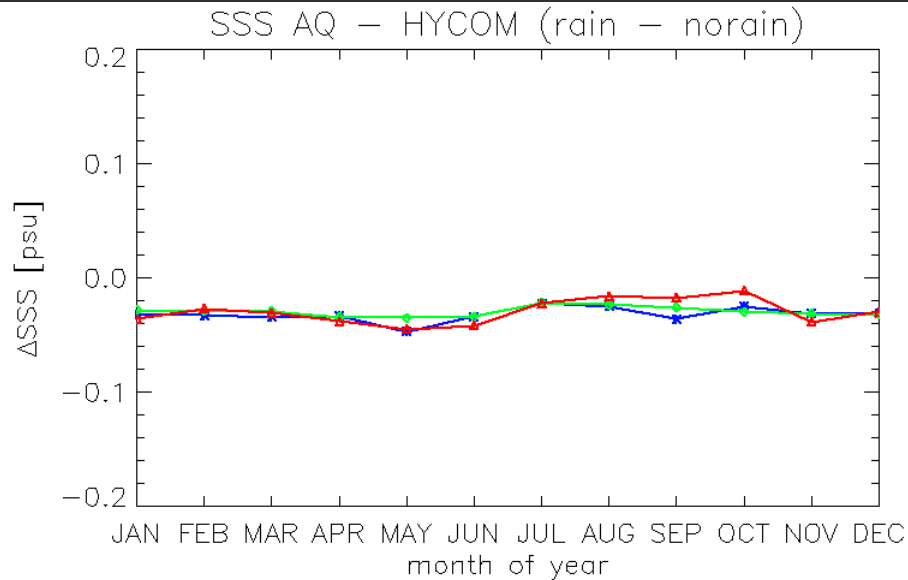

# Aquarius SSS: All Events – Rain Filtered

# Aquarius SSS: All Events – Rain Filtered

## Global Average as Time Series

- **Global difference rain – no-rain is small**
  - 0.04 psu / 0.02 K.
  - Time dependence (month) very weak.
- **Globally it does not rain that much!**
- Compensation to account of the fact that we do not rain filter in calibration can be done
  - Add one-time small TA number for each of the 6 channels in calibration.

# Summary and Conclusions

- MWR rain rates matched to Aquarius are available.
- Atmospheric rain correction has room for improvement.
  - NCEP cloud water auxiliary fields are insufficient for atmospheric correction.
  - Plan: CMORPH
- No or only very small correction for rain splashing effects is warranted, if scatterometer wind speeds are used in the surface roughness correction.
  - The scatterometer wind speed is a good proxy for surface roughness including rain splashing.
- Rain freshening and stratification in upper layer (5 m) visible in data.
- Rain induced freshwater lensing visible in data.
  - Freshening stays on average for 1 - 3 hour.
- Rain impact on calibration loop very small
  - V3.0 does not rain filter in calibration loop.
  - V3.0 SSS are about 0.04 psu too salty.
